About this Manual

This Preface provides general information concerning the scope and organization of this User’s Manual.

Intended Audience

This manual is intended for system administrators responsible for the installation, configuration, management and maintenance of the software and hardware of VPI (InfiniBand, Ethernet) adapter cards. It is also intended for application developers.
## Common Abbreviations and Acronyms

### Table 2 - Abbreviations and Acronyms

<table>
<thead>
<tr>
<th>Abbreviation / Acronym</th>

## Glossary

The following is a list of concepts and terms related to InfiniBand in general and to Subnet Managers in particular. It is included here for ease of reference, but the main reference remains the
Table 3 - Glossary

| Channel Adapter (CA), Host Channel Adapter (HCA) | An IB device that terminates an IB link and executes transport functions. This may be an HCA (Host CA) or a TCA (Target CA). |
| HCA Card | A network adapter card based on an InfiniBand channel adapter device. |
| IB Devices | Integrated circuit implementing InfiniBand compliant communication. |
| In-Band | A term assigned to administration activities traversing the IB connectivity only. |
| Local Port | The IB port of the HCA through which IB DIAG tools connect to the IB fabric. |
| Master Subnet Manager | The Subnet Manager that is authoritative, that has the reference configuration information for the subnet. See Subnet Manager. |
| Multicast Forwarding Tables | A table that exists in every switch providing the list of ports to forward received multicast packet. The table is organized by MLID. |
| Network Interface Card (NIC) | A network adapter card that plugs into the PCI Express slot and provides one or more ports to an Ethernet network. |
| Unicast Linear Forwarding Tables (LFT) | A table that exists in every switch providing the port through which packets should be sent to each LID. |
| Virtual Protocol Interconnect (VPI) | A Mellanox Technologies technology that allows Mellanox channel adapter devices (ConnectX®) to simultaneously connect to an InfiniBand subnet and a 10GigE subnet (each subnet connects to one of the adapter ports). |

1 Overview

This document provides information on the Mellanox driver for FreeBSD and instructions for installing the driver on Mellanox ConnectX® adapter cards supporting the following uplinks to servers:

- ConnectX®-3/ConnectX®-3 Pro:
  - InfiniBand: QDR, FDR10, FDR
  - Ethernet: 10GigE, 40GigE

The driver release introduces the following capabilities:

- Single/Dual port
- Up to 16 Rx queues per port
- Up to 32 Tx queues per port (according to number of CPUs)
- MSI-X or INTx
- Adaptive interrupt moderation
- Hardware Tx/Rx checksum calculation
- Large Send Offload (i.e., TCP Segmentation Offload)
- Large Receive Offload
- VLAN Tx/Rx acceleration (Hardware VLAN stripping/insertion)
- Net device statistics

1.1 Mellanox OFED for FreeBSD Package Contents

1.1.1 Tarball Package

Mellanox OFED for FreeBSD package includes the following directories:

- modules - contains the relevant Makefiles
- ofed - source code

1.1.2 mlx4 driver

mlx4 is the low level driver implementation for the ConnectX adapters designed by Mellanox Technologies. The ConnectX® can operate as an InfiniBand adapter and as an Ethernet NIC.

1.1.2.1 Software Components

Mellanox OFED for FreeBSD contains the following software components:

<table>
<thead>
<tr>
<th>Components</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mlx4_core</td>
<td>Handles low-level functions like device initialization and firmware commands processing. Also controls resource allocation so that the InfiniBand, Ethernet and FC functions can share a device without interfering with each other.</td>
</tr>
<tr>
<td>mlx4_en</td>
<td>Handles Ethernet specific functions and plugs into the netdev mid-layer.</td>
</tr>
</tbody>
</table>
### Table 5 - Mellanox OFED for FreeBSD Software Components

2 Installation

This chapter describes how to install and test the Mellanox driver for FreeBSD package on a single host machine with Mellanox InfiniBand and/or Ethernet adapter hardware installed.

2.1 Software Dependencies

- To install the driver software, kernel sources must be installed on the machine.
- To run the Packet Pacing feature, the kernel patch and dedicated FW version included in the Packet Pacing package need to be applied.

2.2 Downloading Mellanox Driver for FreeBSD

1. Verify that the system has a Mellanox network adapter (HCA/NIC) installed. The following example shows a system with an installed Mellanox HCA:

   ```bash
   # pciconf -lv | grep Mellanox -C 3
   mlx4_core0@pci0:7:0:0:  class=0x028000 card=0x000615b3 chip=0x100315b3 rev=0x00 hdr=0x00
   vendor     = 'Mellanox Technologies'
   device     = 'MT27500 Family [ConnectX-3]'
   class      = network
   ```

2. Download the tarball image to your host. The image name has the format MLNX_OFED_FreeBSD-<ver>.tgz. You can download it from [http://www.mellanox.com > Products > Software > Ethernet Drivers > FreeBSD](http://www.mellanox.com > Products > Software > Ethernet Drivers > FreeBSD) or [http://www.mellanox.com > Products > Software > InfiniBand/VPI drivers > FreeBSD](http://www.mellanox.com > Products > Software > InfiniBand/VPI drivers > FreeBSD)

3. Use the md5sum utility to confirm the file integrity of your tarball image.

2.3 Installing Mellanox Driver for FreeBSD

1. Extract the tarball.

2. Compile and load needed modules in the following order of dependencies:

   - Ethernet Driver:
     ```bash
     mlx4_core
     ```

     a. Go to the mlx4 directory. Run:

     ```bash
     # cd modules/mlx4
     ```

     b. Clean any previous dependencies. Run:

     ```bash
     # make -n $HEAD/share/mk SYSDIR=$HEAD/sys clean cleandepend
     ```

Prior to installing the driver, please re-compile (and install) the kernel with NO OFED options/devices enabled.
c. Compile the mlx4_core module. Run:

```
# make -n $HEAD/share/mk SYSDIR=$HEAD/sys
```

**Note:** For packet pacing support, add `CONFIG_RATELIMIT=yes`. This option has a kernel patch dependency.

d. Install the mlx4_core module. Run:

```
# make -n $HEAD/share/mk SYSDIR=$HEAD/sys install
```

e. Load the mlx4_core module. Run:

```
# kldload mlx4
```

**mlxen**

a. Go to the mlxen directory. Run:

```
# cd modules/mlxen
```

b. Clean any previous dependencies. Run:

```
# make -n $HEAD/share/mk SYSDIR=$HEAD/sys clean cleandepend
```

c. Compile the mlxen module. Run:

```
# make -n $HEAD/share/mk SYSDIR=$HEAD/sys
```

**Note:** For packet pacing support, add `CONFIG_RATELIMIT=yes`. This option has a kernel patch dependency.

d. Install the mlxen module. Run:

```
# make -n $HEAD/share/mk SYSDIR=$HEAD/sys install
```

e. Load the mlxen module. Run:

```
# kldload mlxen
```

- **InfiniBand Driver:**

  **mlx4_core**

  Run the same steps as specified for Ethernet driver above.

  **ib_core**

  a. Go to the ib_core directory. Run:

  ```
  # cd modules/ibcore
  ```

  b. Clean any previous dependencies. Run:

  ```
  # make -n $HEAD/share/mk SYSDIR=$HEAD/sys clean cleandepend
  ```

  c. Compile the ib_core module. Run:

  ```
  # make -n $HEAD/share/mk SYSDIR=$HEAD/sys
  ```

  d. Install the ib_core module. Run:

  ```
  # make -n $HEAD/share/mk SYSDIR=$HEAD/sys install
  ```

  e. Load the ib_core module. Run:

  ```
  # kldload ibcore
  ```

  **mlx4_ib**

  a. Go to the mlx4_ib directory. Run:

  ```
  # cd modules/mlx4ib
  ```
b. Clean any previous dependencies. Run:

```
# make -m $HEAD/share/mk SYSDIR=$HEAD/sys clean cleandepend
```

c. Compile the mlx4_ib module. Run:

```
# make -m $HEAD/share/mk SYSDIR=$HEAD/sys
```

d. Install the mlx4_ib module. Run:

```
# make -m $HEAD/share/mk SYSDIR=$HEAD/sys install
```

e. Load the mlx4_ib module. Run:

```
# kidload mlx4ib
```

**ipoib**

a. Go to the ipoib directory. Run:

```
# cd modules/ipoib
```

b. Clean any previous dependencies. Run:

```
# make -m $HEAD/share/mk SYSDIR=$HEAD/sys clean cleandepend
```

c. Compile the ipoib module. Run:

```
# make -m $HEAD/share/mk SYSDIR=$HEAD/sys
```

d. Install the ipoib module. Run:

```
# make -m $HEAD/share/mk SYSDIR=$HEAD/sys install
```

e. Load the ipoib module. Run:

```
# kidload ipoib
```

To load a module on reboot, add "mlx4_load="YES"/mlxen_load="YES"/ibcore_load="YES"/
mlx4ib_load="YES"/ipoib="YES"" to the '/boot/ loader.conf' file (create if does not exist).

Run "kldstat" in order to verify which modules are loaded on your server.

## 2.4 Firmware Programming

The adapter card was shipped with the most current firmware available. This section is intended for future firmware upgrades, and provides instructions for (1) installing Mellanox firmware update tools (MFT), (2) downloading FW, and (3) updating adapter card firmware.

### 2.4.1 Installing Firmware Tools

**Step 1.** Download the current Mellanox Firmware Tools package (MFT) from www.mellanox.com > Products > Adapter IB/VPI SW > Firmware Tools.

The tools package to download is "MFT_SW for FreeBSD" (tarball name is mft-X.X.X.tgz).

**Step 2.** Extract the tarball and run the installation script.
2.4.2 Downloading Firmware
1. Retrieve device's PCI slot (i.e. pci0:x:0:0). Run:

   $ mst status

2. Verify your card’s PSID.

   $flint -d <pci> q

3. Download the desired firmware from the Mellanox website.

   http://www.mellanox.com/page/firmware_download

2.4.3 Updating Firmware Using flint
1. Unzip the firmware binary file:

   $flint -d <pci> -i <img.bin> b

2. Reboot the server.

2.4.4 Updating Firmware Using mlxburn (.mlx file)
1. Extract the relevant firmware package (ConnectX3/ConnectX3-Pro).
2. From the extracted directory, run:

   $mlxburn -d <NIC's_pci_slot> -fw <.mlx file> -conf_dir_list .

   Example

   $mlxburn -d <NIC's_pci_slot> -fw fw-ConnectX3-rel.mlx -conf_dir_list .

3. Reboot the server.

2.5 Driver Usage and Configuration

   ➢ To assign an IP address to the interface:

   #> ifconfig mlxen<x> <ip>

   Note: <x> is the OS assigned interface number

   ➢ To check driver and device information:

   #> pciconf -lv | grep mlx
   #> flint -d pci<w:x:y:z> q

   Example:

   #> pciconf -lv | grep mlx
   mlx4_core0@pci0:7:0:0:  class=0x028000 card=0x003715b3 chip=0x100315b3 rev=0x00 hdr=0x00
   #> flint -d pci0:7:0:0 q
   Image type:      FS2
   FW Version:      2.11.1294
   Device ID:       4099
   Description:     Node             Port1            Port2            Sys image
   GUIDs:           0002c903002ffcc0 0002c903002ffcc1 0002c903002ffcc2 0002c903002ffcc3
   MACs:                                 0002c92ffcc0     0002c92ffcc1
   VSD:
   PSID:            MT_1020120019
To check driver version:

```bash
#> dmesg
```

Example:

```bash
#> dmesg
mlx4_core: Mellanox ConnectX core driver v2.1 (Aug 21 2014)
mlx4_en: Mellanox ConnectX HCA Ethernet driver v2.1 (Aug 18 2014)
```

To query stateless offload status:

```bash
#> ifconfig mlxen<x>
```

Note: `<x>` is the OS assigned interface number

To set stateless offload status:

```bash
#> ifconfig mlxen<x> [rxcsum|-rxcsum] [txcsum|-txcsum] [tso|-tso] [lro|-lro]
```

Note: `<x>` is the OS assigned interface number

To query interrupt coalescing settings:

```bash
#> sysctl -a | grep adaptive
```

Example:

```bash
#> sysctl -a | grep adaptive
hw.mlxen0.conf.adaptive_rx_coal: 1
hw.mlxen1.conf.adaptive_rx_coal: 1
```

To enable/disable adaptive interrupt moderation:

```bash
#> sysctl hw.mlxen<x>.conf.adaptive_rx_coal=[1/0]
```

Note: `<x>` is the OS assigned interface number

By default, the driver uses adaptive interrupt moderation for the receive path, which adjusts the moderation time to the traffic pattern.

To query values for packet rate limits and for moderation time high and low:

```bash
#> sysctl -a | grep pkt_rate
#> sysctl -a | grep rx_usecs
```

To set the values for packet rate limits and for moderation time high and low:

```bash
#> sysctl hw.mlxen<x>.conf.pkt_rate_low=[N]
#> sysctl hw.mlxen<x>.conf.pkt_rate_high=[N]
#> sysctl hw.mlxen<x>.conf.rx_usecs_low=[N]
#> sysctl hw.mlxen<x>.conf.rx_usecs_high=[N]
```

Note: `<x>` is the OS assigned interface number

Example:

```bash
#> sysctl -a | grep pkt_rate
hw.mlxen0.conf.pkt_rate_low: 400000
hw.mlxen0.conf.pkt_rate_high: 450000
hw.mlxen1.conf.pkt_rate_low: 400000
hw.mlxen1.conf.pkt_rate_high: 450000
#> sysctl -a | grep rx_usecs
hw.mlxen0.conf.rx_usecs_low: 0
hw.mlxen0.conf.rx_usecs_high: 128
hw.mlxen1.conf.rx_usecs_low: 0
hw.mlxen1.conf.rx_usecs_high: 128
```
Above an upper limit of packet rate, adaptive moderation will set the moderation time to its highest value. Below a lower limit of packet rate, the moderation time will be set to its lowest value.

- **To query pause frame settings:**
  
  ```
  #> ifconfig -m mlxen<x>
  ```

  **Note:** `<x>` is the OS assigned interface number

- **To set pause frame settings:**
  
  ```
  #> ifconfig -m mlxen<x> [-]mediaopt [rxpause,txpause]
  ```

  **Note:** `<x>` is the OS assigned interface number

- **To query ring size values:**
  
  ```
  #> sysctl -a | grep _size
  ```

  **Example:**

  ```
  #> sysctl -a | grep _size
  hw.mlxen0.conf.rx_size: 1024
  hw.mlxen0.conf.tx_size: 1024
  hw.mlxen1.conf.rx_size: 1024
  hw.mlxen1.conf.tx_size: 1024
  ```

- **To modify rings size:**
  
  ```
  #> sysctl hw.mlxen<x>.conf.rx_size=[N]
  #> sysctl hw.mlxen<x>.conf.tx_size=[N]
  ```

  **Note:** `<x>` is the OS assigned interface number

- **To obtain additional device statistics:**
  
  ```
  #> sysctl -a | grep mlx | grep stat
  ```

The driver defaults to the following parameters:

- Both ports are activated (i.e., a net device is created for each port)
- The number of Rx rings for each port is the nearest power of 2 of number of CPU cores, limited by 16.
- LRO is enabled with 32 concurrent sessions per Rx ring
3 Features Overview and Configuration

3.1 Ethernet Network

3.1.1 RDMA over Converged Ethernet (RoCE)

RoCE allows InfiniBand (IB) transport applications to work over an Ethernet network. RoCE encapsulates the InfiniBand transport and the GRH headers in Ethernet packets bearing a dedicated ether type (0x8915). Thus, any VERB application that works in an InfiniBand fabric can also work in an Ethernet fabric.

RoCE is enabled only for drivers that support VPI (currently, only mlx4).

- When working with RDMA applications over Ethernet link layer, the following points should be noted:
  - The presence of a Subnet Manager (SM) is not required in the fabric. Thus, operations that require communication with the SM are managed in a different way in RoCE. This does not affect the API.
  - Since the SM is not present, querying a path is impossible. Therefore, the path record structure must be filled with the relevant values before establishing a connection. It is recommended working with RDMA-CM to establish a connection as it takes care of filling the path record structure.
  - Since LID is a layer 2 attribute of the InfiniBand protocol stack, it is not set for a port and is displayed as zero when querying the port.
  - With RoCE, APM is not supported.
  - The GID table for each port is populated with N+1 entries where N is the number of IP addresses that are assigned to all network devices associated with the port including VLAN devices.
  - The first entry in the GID table (at index 0) for each port is always present and equal to the link local IPv6 address of the net device that is associated with the port. Note that even if the link local IPv6 address is not set, index 0 is still populated.
  - GID format can be of 2 types, IPv4 and IPv6. IPv4 GID is a IPv4-mapped IPv6 address while IPv6 GID is the IPv6 address itself.
  - Load the following modules for RoCE support: mlx4_core, ib_core, mlx4_ib, and mlx4_en.

---

1. For the IPv4 address A.B.C.D the corresponding IPv4-mapped IPv6 address is ::ffff.A.B.C.D
3.1.2 Packet Pacing
Packet pacing, also known as the “rate limit,” defines a maximum bandwidth allowed for a TCP connection. Limitation is done by hardware where each QP (transmit queue) has a rate limit value from which it calculates the delay between each packet sent.

3.1.2.1 Setting Properties for Packet Pacing
Before loading mlxen module, set which property (0-7) is relevant for packet pacing sockets. Run:

```bash
kenv hw.mlx4_en.config_prios_for_rl_rings=<#priority>,<#priority>,<#priority>...
```

For example:

```bash
kenv hw.mlx4_en.config_prios_for_rl_rings=0,1,2...
```

When no priorities are being selected, the default priority supported with packet pacing sockets would be priority zero.

3.1.2.2 Setting Rates for Packet Pacing
Rates that are being used with packet pacing must be defined in advance.

**New Rates Configuration**

- Newly configured rates must be within a certain range, determined by the firmware, and they can be read through `sysctl`.
  - For a minimum value, run:
    ```bash
    #sysctl sys.device.<DEVICE NAME>.rate_limit_caps.min_value
    ```
  - For a maximum value, run:
    ```bash
    #sysctl sys.device.<DEVICE NAME>.rate_limit_caps.max_value
    ```

- The number of configured rates is also determined by the firmware. In order to check how many rates can be defined, run:
  ```bash
  #sysctl hw.<INTERFACE NAME>.conf.num_rates
  ```

- A new rate can be added by any the following methods:
  - Add a rate per index (from index 1 to num_rates):
    ```bash
    #sysctl hw.<INTERFACE NAME>.conf.rate_limit_1=400000
    #sysctl hw.<INTERFACE NAME>.conf.rate_limit_120=500000
    ```

  In order to read which rate was defined for a specific index (for example, Index 1), run:
  ```bash
  #sysctl hw.<INTERFACE NAME>.conf.rate_limit_1
  ```

  ![Pen](image)

  Each index can be defined with a rate only once.

  - Add a rate in an unknown index:
    ```bash
    #sysctl hw. <INTERFACE NAME>.conf.add_rate=600000
    ```
This will add the defined rate to the next available index. If all rates were already defined with an index, the new rate will not be added.

Rates are determined and then saved in bits per second. Rates requested for a new socket are added in bytes per second.

**Limitation:** Rate values must be multiples of 1000.

- There are two burst levels that can be defined for each index:
  - **Burst low:** Burst capacity is limited to a lower range to allow better pacing
  - **Burst high:** Burst capacity is limited to a higher range to allow better bandwidth

For changing the burst level per index, run:

```bash
#sysctl hw. <INTERFACE NAME>.conf.burst_size_1=burst_high/burst_low
```

In order to read which burst level was defined for an index (for example, index 1), run:

```bash
#sysctl hw. <INTERFACE NAME>.conf.burst_size_1
```

- To display the packet pacing configuration, run:

```bash
#sysctl hw. <INTERFACE NAME>.conf.rate_limit_limit_show
```

<table>
<thead>
<tr>
<th>INDEX</th>
<th>CURRENTLY USED BURST</th>
<th>RATE [bit/s]</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>HIGH</td>
<td>400,000</td>
</tr>
<tr>
<td>2</td>
<td>LOW</td>
<td>500,000</td>
</tr>
<tr>
<td>3</td>
<td>LOW</td>
<td>0</td>
</tr>
<tr>
<td>4</td>
<td>LOW</td>
<td>0</td>
</tr>
</tbody>
</table>

where:

- **Index** Rate index
- **Currently used** number of rings which are currently running, configured with the index's rate
- **Burst** Burst level configured for the index's rate
- **Rate** Rate configured for the relevant index

All rates are shown in bits per second.

### 3.1.2.3 Using Packet Pacing Sockets

1. Create a rate-limited socket according to the desired rate using the `setsockopt()` interface based on the previous section:

```bash
setsockopt(s, SOL_SOCKET, SO_MAX_PACING_RATE, pacing_rate, sizeof(pacing_rate))
```

- **SO_MAX_PACING_RATE** Marks the socket as a rate limited socket
- **pacing_rate** Defined rate in bytes/sec. The type is unsigned int.

**Note:** The same value entered via `sysctl` in bytes instead of bits.
• A rate-limited ring corresponding to the requested rate will be created and associated to the relevant socket.
• Rate-limited traffic will be transmitted when data is sent via the socket.

2. Modify the rate-limited value using the same socket.
3. Destroy the relevant ring upon TCP socket completion.

3.1.2.3.1 Error Detection
Detecting failures can be done using the getsockopt() interface to query a specific socket.

```c
getsockopt(s, SOL_SOCKET, SO_MAX_PACING_RATE, pacing_rate, &size_socket);
```

- `pacing_rate`: Holds the rate limit value associated with the socket. If the value of pacing_rate=0, it means that there was an error and the rate limit could not be set on the socket, and the socket is not rate-limited. For a more detailed message, look at the output of dmesg.

To see if the socket is rate-limited, data must be sent using the socket. Only then will the getsockopt returned value be valid.

3.1.2.4 Feature Characteristics

- MLNX_OFED for FreeBSD supports up to 45,000 rate limited TCP connections.
- Each TCP connection is mapped to a specific QP
- **User interface**
  - Rate limited tx ring amount:
    ```bash
    #> sysctl -a | grep rate_limit_tx_ring
    hw.mlxen0.conf.rate_limit_tx_rings: 0
    hw.mlxen1.conf.rate_limit_tx_rings: 0
    ```
  - Native tx ring amount:
    ```bash
    #> sysctl -a | grep native_tx_ring
    hw.mlxen0.conf.native_tx_rings: 8
    hw.mlxen1.conf.native_tx_rings: 8
    ```

- **Debugging**
  - Setting the kernel environment variable before loading the modules:
    ```bash
    #> kenv rate.limit.debug=1
    ```
  - All rate limited rings statistics will be available via Sysctl (as debug option is enabled):
    - Rate limit value
    - Packets
    - Bytes
    ```bash
    #> sysctl -a | grep tx_ring
    hw.mlxen0.stat.tx_ring8.rate_limit_val: 409600
    ```
3.1.2.5 Limitations

- Max rate limited rings is 45,000
- Min rate: 250 Kbps
- Max rate: 50 Mbps

```
#> sysctl -a | grep rate_limit_caps
sys.device.mlx4_core0.rate_limit_caps.min_value: 250 Kbps
sys.device.mlx4_core0.rate_limit_caps.max_value: 50 Mbps
```

- Different rate limits to be configured per NIC/port: 120 divided by the number of priorities (See Section 3.1.2.1)

3.1.3 EEPROM Cable Module Information Reader

In order to read the cable EEPROM info:

- Read the cable information by enabling the following sysctl parameter:

```
sysctl hw.mlxen<X>.conf.eeprom_info=1
```

**Example**

```
<table>
<thead>
<tr>
<th>Offset</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0000</td>
<td>0d 02 06 00 00 00 00 00 00 00 00 00 00 00 00 00</td>
</tr>
<tr>
<td>0x0010</td>
<td>00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00</td>

</tr>
<tr>
<td>0x00f0</td>
<td>00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00</td>
</tr>
</tbody>
</table>
```
4 Performance Tuning

4.1 Interrupt Moderation

Interrupt moderation is used to decrease the frequency of network adapter interruptions to the CPU. Mellanox network adapters use an adaptive interrupt moderation algorithm by default. The algorithm checks the transmission (Tx), receives (Rx) packet rates and modifies the Rx interrupt moderation settings accordingly.

In order to manually set Rx interrupt moderation, use sysctl:

**Step 1.** Turn OFF the interrupt moderation. Run:

```
#> sysctl hw.mlxen<x>.conf.adaptive_rx_coal=0
```

*Note:* `<x>` is the OS assigned interface number

**Step 2.** Turn ON the interruption moderation. Run:

```
#> sysctl hw.mlxen<xa>.conf.adaptive_rx_coal=1
```

**Step 3.** Set the threshold values for packet rate limits and for moderation time. Run:

```
#> sysctl hw.mlxen<xa>.conf.pkt_rate_low=[N]
#> sysctl hw.mlxen<xa>.conf.rx_usecs_low=[N]
#> sysctl hw.mlxen<xa>.conf.pkt_rate_high=[N]
#> sysctl hw.mlxen<x>.conf.rx_usecs_high=[N]
```

Above an upper limit of packet rate, adaptive moderation will set the moderation time to its highest value. Below a lower limit of packet rate, the moderation time will be set to its lowest value.

4.2 Tuning for NUMA Architecture

4.2.1 Single NUMA Architecture

When using a server with single NUMA, no tuning is required. Also, make sure to avoid using core number 0 for interrupts and applications.

1. Find a CPU list:

```
sysctl -a | grep "group level="2\"" -A 1
<group level="2" cache-level="2">
<cpu count="12" mask="fff">0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11</cpu>
```

2. Tune Mellanox NICs to work on desirable cores

   a. Find the NIC's PCI location:

```
pciconf -lv | grep mlx
mlx4_core0@pci0:2:0:0: class=0x028000 card=0x000315b3 chip=0x100715b3 rev=0x00 hdr=0x00
```

   b. Find the NIC's device name by its PCI location

```
sysctl -a | grep pci2
dev.mlx4_core.0.%parent: pci2
```
This means the NIC on PCI number 2 has a logic device called mlx4_core0.

a. Find the device interrupts.

```
vmstat -ia | grep mlx4_core0 | awk '{print $1}' | sed s/irq// | sed s/://
```

285
286
287
...

b. Bind each interrupt to a desirable core.

```
cpuset -x 285 -l 1
cpuset -x 286 -l 2
cpuset -x 287 -l 3
...
```

c. Bind the application to the desirable core.

```
cpuset -l 1-11 <app name> <server flag>
cpuset -l 1-11 <app name> <client flag> <IP>
```

Specifying a range of CPUs when using the cpuset command will allow the application to choose any of them. This is important for applications that execute on multiple threads. The range argument is not supported for interrupt binding.

### 4.2.2 Dual NUMA Architecture

1. Find the CPU list closest to the NIC

a. Find the NIC’s PCI location:

```
pciconf -lv | grep mlx
mlx4_core0@pci0:4:0:0: class=0x028000 card=0x000315b3 chip=0x100715b3 rev=0x00 hdr=0x00
```

Usually, low PCI locations are closest to NUMA number 0, and high PCI locations are closest to NUMA number 1. Here is how to verify the locations:

b. Find the NIC’s pcib by PCI location (in this example, try PCI 4)

```
sysctl -a | grep pci.4.%paren
dev.pci.4.%parent: pcib3
```

c. Find the NIC’s pcib location:

```
sysctl -a | grep pcib.3.%location
dev.pcib.3.%location: slot=2 function=0 handle=\_SB\_PCI0.NPE3
```

In "handle", PCI10 is the value for locations near NUMA0, and PCI11 is the value for locations near NUMA1.

d. Find the cores list of the closest NUMA:

```
sysctl -a | grep *group level="2"* -A 1
<group level="2" cache-level="2">  
<cpu count="12" mask="fff">0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11</cpu>  
</group level="2" cache-level="2">  
<cpu count="12" mask="fff000">12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23</cpu>
```

**Note:** Each list of cores refers to a different NUMA.
2. Tune Mellanox NICs to work on desirable cores.
   a. Pin both interrupts and application processes to the relevant cores.
   b. Find the closest NUMA to the NIC
   c. Find the NIC’s device name by its PCI location.

```
sysctl -a | grep pci4
dev.mlx4_core.0.%parent: pci4
```

This means the NIC on PCI number 4 has a logic device called mlx4_core0.

d. Find the device interrupts.

```
vmsstat -ia | grep mlx4_core0 | awk '{print $1}' | sed s/irq/// | sed s/://
```

```
338
339
340
...
```
e. Bind each interrupt to a core from the closest NUMA cores list

**Note:** It is best to avoid core number 0.

```
cpuset -x 338 -l 1
cpuset -x 339 -l 2
cpuset -x 340 -l 3
...
```
f. Bind the application to the closest NUMA cores list.

**Note:** It is best to avoid core number 0

```
cpuset -l 1-11 <app name> <server flag>
cpuset -l 1-11 <app name> <client flag> <IP>
```

For best performance, change CPU’s BIOS configuration to performance mode.
